#### 功能性腦成像之機器學習分類於帕金森氏症病期預測

1

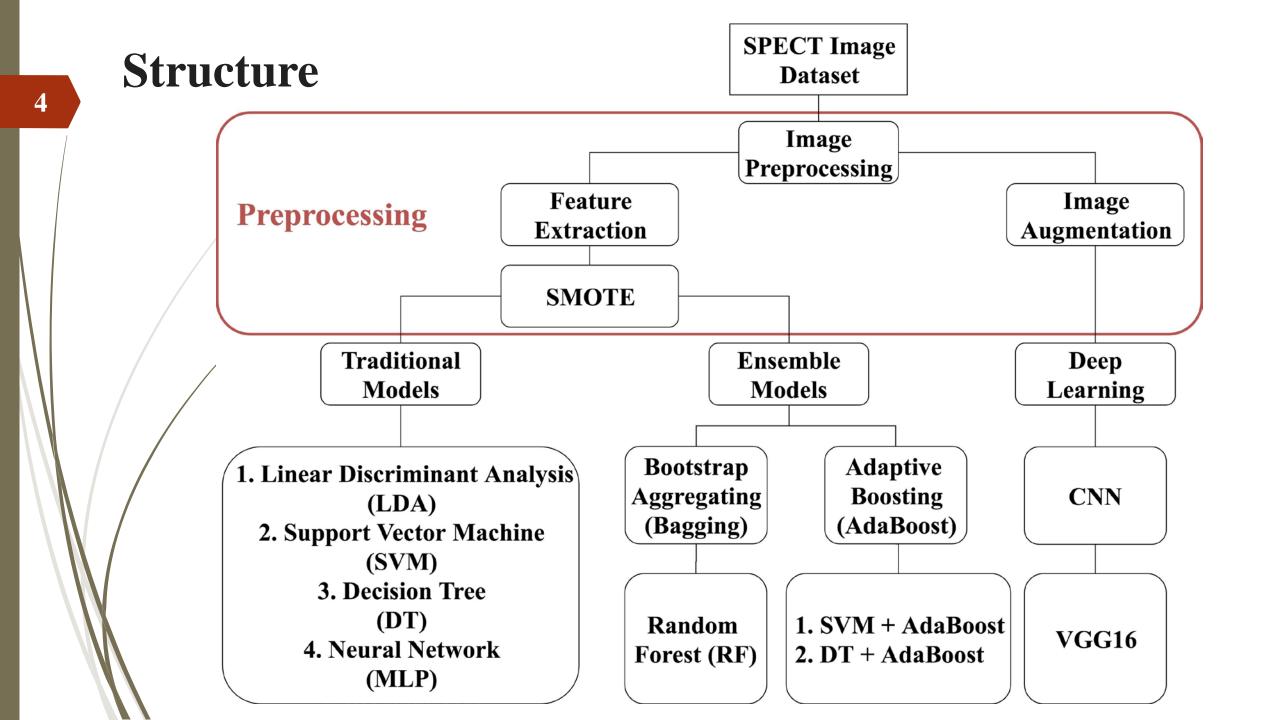

林芷瑄、黄冠華\* 國立交通大學 統計學研究所

- Parkinson's disease (PD) : degenerative neurological disorder related to striatal dopamine deficiency
- Symptoms : slow movement, muscle stiffness and shaking
  Prevalence :
  - 60.1% ~0.2% among the general population
  - ► 2% among people aged over 65 years.
  - ► In Taiwan, the prevalence of PD is in a 7.9% yearly increase.
- Detection of PD : functional imaging, ex. SPECT, PET

#### Analysis Methods :

- Voxels of the complete brain + dimensional reduction
- Voxels of striatum + feature selection or striatal binding ratio value
- Shape and intensity distribution analysis
- Researchers have developed a number of methods for classifying subjects as either healthy or suffering from PD.
- We developed system including a series of methods to deal with the multi-classes classification problem in PD stages.
- This system includes image preprocessing, imbalanced data preprocessing, and three kinds of models: traditional model, ensemble model and deep learning model.

#### Dataset

- Retrospective Experiment Designed
- Collect Time : from March 2006 to May 2014
- Data : 99mTc-TRODAT-1 SPECT Imaging
- Imaging Format : DICOM (Digital Imaging and Communications in Medicine)
- Sample Size: : 202 with 3D volume (128 pixel \* 128 pixel \* *n* slices)

Stage	Normal	Stage I	Stage II	Stage III	Stage IV	Stage V
Sample Size	6	22	27	53	87	7
Percentage	3%	11%	13%	26%	43%	3%

#### **Feature Extraction – PCA**

- A principle component analysis (PCA) is concerned with explaining the variance-covariance structure of a set of variables through a few "linear" combinations of these variables.
  - Objectives of a principle component analysis:
    - Dimension reduction: the total variability of p variables can be accounted for by k principle components, where p > k.

5	1	1	2	2	1					
Total	41	41	40	40	40					

#### **Imbalanced Data**

10

- Under-sampling : This method will random pick samples from the majority classes until each classes is balanced or reach the requirement. The rest part of the majority classes samples will be ignored.
  - Advantage : increasing the sensitivity of a classifier to minority class.
  - Disadvantage : discard potentially useful information
  - Over-sampling : New minority class data will be drawn with replacement by the original data until each classes is balanced. It directly repeat the samples from the minority classes.
    - Advantage : Unlike under-sampling, this method leads to no information loss.
    - Disadvantage : It increases the likelihood of overfitting since it replicates the minority class events.

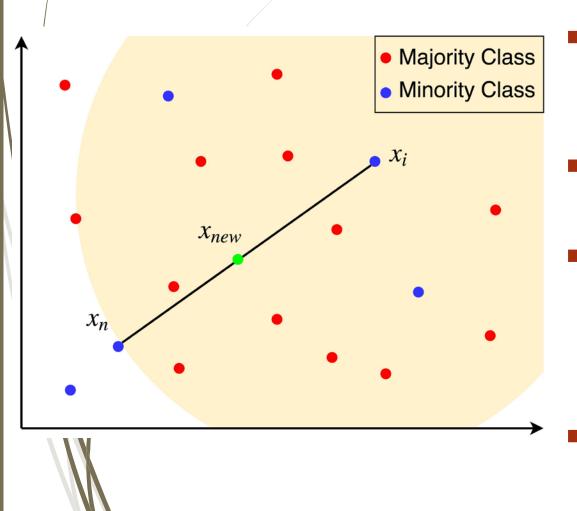

Methods

Results

Conclusion

# **Over-sampling – SMOTE**

11

- Step 1 : Considering a sample x<sub>i</sub> belonging to minority class, select k nearest-neighbors, which also belong to minority class.
- Step 2 : Randomly pick a sample  $x_n$  from these *k* nearest-neighbors.
- Step 3 : A new sample  $x_{new}$  is generated as follows:

$$x_{new} = x_i + \lambda * |x_n - x_i|$$

where  $\lambda$  is a random number in the range [0, 1].

Step 4 : Repeat step 1 to step 3 until the minority sample size is reach the requirement.

Results

#### **Image Augmentation**

- Image augmentation artificially creates training images through different ways of processing or combination of multiple processing.
- Traditional transformations : using a combination of affine transformations to manipulate the training data
- For each input image, we generate **duplicate** images that are shifted, zoomed in/out, rotated, flipped, distorted, or shaded with a hue.

Classification Rule  $f(\boldsymbol{x}) = \boldsymbol{w}^T \boldsymbol{x} + b = \sum_{i=1}^{T} w_i x_i + b = 0$  $G(\boldsymbol{x}) = sign(\boldsymbol{w}^T \boldsymbol{x} + b)$  $y = \begin{cases} 1, \text{ if } G(\boldsymbol{x}) \ge 0\\ -1, \text{ if } G(\boldsymbol{x}) < 0 \end{cases}$ 

Optimization Problem  $\max_{\boldsymbol{w}, b, \|\boldsymbol{w}\|=1} M$ subject to  $y_i(\boldsymbol{w}^T \boldsymbol{x}_i + b) \ge M, i = 1, \dots, N$ 

Objective Function  $\min_{\boldsymbol{w}, b} \|\boldsymbol{w}\|$ subject to  $y_i(\boldsymbol{w}^T \boldsymbol{x} + b) \ge 1, i = 1, \dots, N$  Methods

Results

Conclusion

## **Decision Tree (DT) – CART**

• Step 1 : Let the data at node *m* be represented by  $D^m$ . For each candidate split  $\theta = (j, t_a)$  consisting of a feature *j* and threshold  $t_a$ , partition the data into  $D_{left}^m(\theta)$  and  $D_{right}^m(\theta)$  subsets.

$$D_{left}^{m}(\theta) = (j, y) | j \le t_{a}$$
$$D_{right}^{m}(\theta) D^{m} \setminus D_{left}^{m}(\theta)$$

Step 2: For each candidate split  $\theta$ , the impurity at m is computed using an impurity function  $H(\cdot)$ . For CART,  $H(\cdot)$  is Gini impurity.

$$G(D^{m},\theta) = \frac{n_{left}}{N_{m}} H\left(D_{left}^{m}(\theta)\right) + \frac{n_{right}}{N_{m}} H\left(D_{right}^{m}(\theta)\right)$$

Gini Impurity :  $p_{mk} = \frac{1}{N_m} \sum_{x_i \in R_m} I(y_i = k) \Rightarrow H(D_m) = \sum_k p_{mk}(1 - p_{mk})$ 

- Step 3 : Select the parameters that minimize the impurity.  $\theta^* = \underset{\theta}{\operatorname{argmin}} G(D^m, \theta)$
- Step 4 : Recurse for subsets  $D_{left}^{m}(\theta^{*})$  and  $D_{right}^{m}(\theta^{*})$  until the maximum allowable depth is reached,  $N_{m} < \min_{samples} or N_{m} = 1$ .

# **Ensemble Learning**

Results

### **Ensemble Learning**

- Averaging methods : The driving principle is to build several estimators independently and then to average their predictions. On average, the combined estimator is usually better than any of the single base estimator because its variance is reduced.
  - Example : Bagging, *Random Forest*
  - **Boosting methods** : Base estimators are built sequentially and one tries to reduce the bias of the combined estimator. The motivation is to combine several weak models to produce a powerful ensemble.
    - Example : *Adaptive Boosting*, Gradient Tree Boosting

Methods

Results

Conclusion

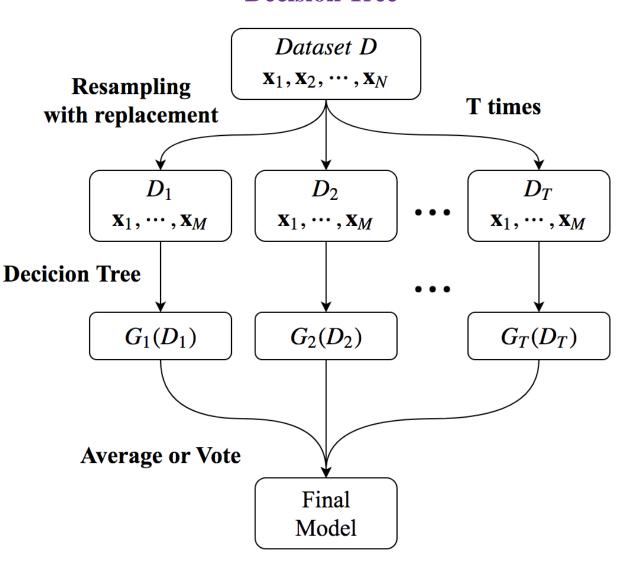

### **Random Forest (RF)**

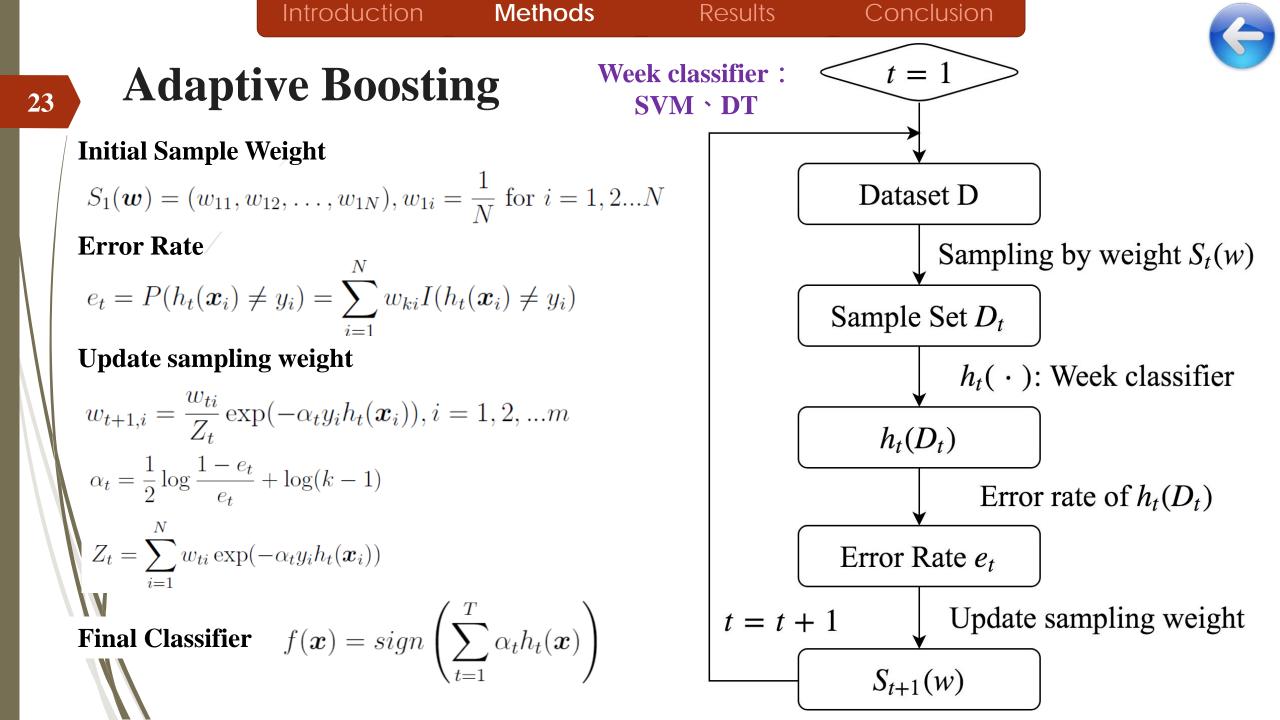

- For a given number of trees T in the forest and dataset D
- (1) For  $t = 1, 2, \dots, T$ :

22

- (a) Dataset  $D_t$  is drawn with replacement from D at random.
- (b) Construct decision tree  $G_t(\mathbf{x})$  by  $D_t$ .
- (2) For classification problem, the class that the most classifier vote for is the final class.

# **Transfer Learning – VGG16**

#### Transfer Learning :

- Transfer learning is a machine learning technique where a model trained on one task is repurposed on a second related task.
- Transfer knowledge across tasks, instead of generalizing within a specific task.
- For example, transfer image recognition knowledge from a cat recognition app to a radiology diagnosis.

#### VGG16 (Visual Geometry Group) :

- One of the best CNN model proposed (by Alex Krizhevsky et al) in 2014.
- At the ILSVRC 2014 competition, an ensemble of two VGG Networks (VGG16 and VGG19) received a top-5 error of 7.3%

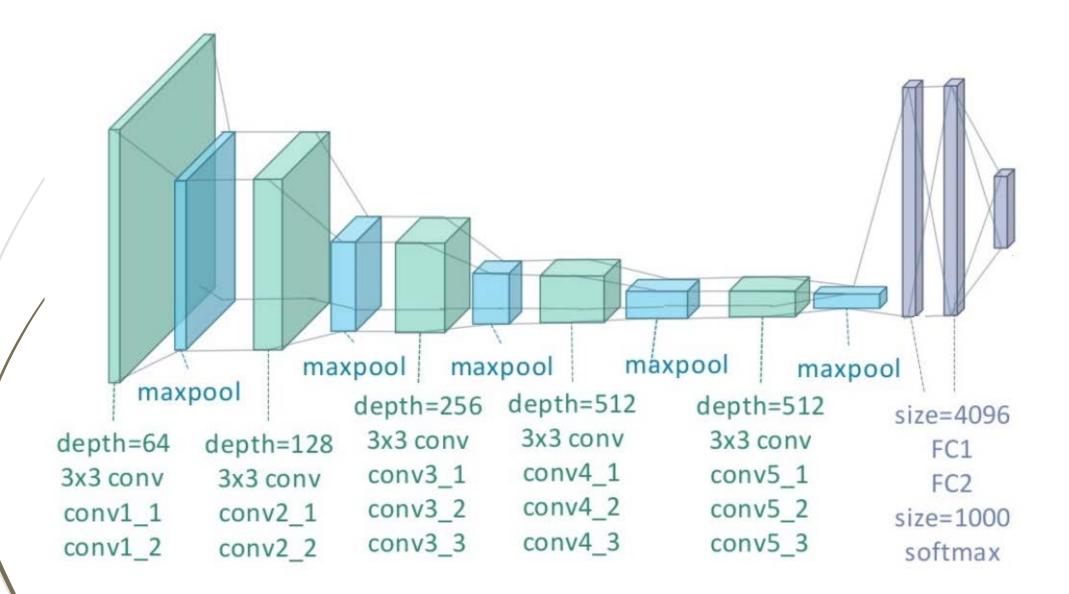

Methods

Results

# Conclusion

#### Conclusion

- We developed system including a series of methods to deal with the multi-classes classification problem in PD stages.
- This system includes image preprocessing, imbalanced data preprocessing, and three kinds of models: traditional model, ensemble model and deep learning model.
- Overall, VGG16 outperforms other models.
- VGG16 and its related image preprocessing is a useful and better approach to develop multi-classes classification model.

#### Future work :

- Take advantage of the whole 3D brain imaging.
- Investigate other advanced deep learning model, such as VGG19, ResNet50, Xception, Inception etc.

# THE END

Thank You
